

Lambda Calculus

Your Favorite Language

Probably has lots of features:

- Assignment ($x = x + 1$)
- Booleans, integers, characters, strings, ...
- Conditionals
- Loops
- `return`, `break`, `continue`
- Functions
- Recursion
- References / pointers
- Objects and classes
- Inheritance
- ...

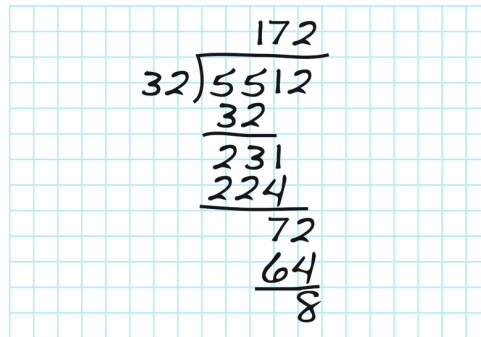

Which ones can we do without?

What is the **smallest universal language**?

What is computable?

Before 1930s

Informal notion of an **effectively calculable** function:

$$\begin{array}{r} 172 \\ 32 \overline{) 5512} \\ \underline{32} \\ 231 \\ \underline{224} \\ 72 \\ \underline{64} \\ 8 \end{array}$$

can be computed by a human with pen and paper, following an algorithm

1936: Formalization

What is the **smallest universal language**?

Alan Turing

Alonzo Church

The Next 700 Languages

Peter Landin

Whatever the next 700 languages turn out to be, they will surely be variants of lambda calculus.

Peter Landin, 1966

The Lambda Calculus

Has one feature:

- Functions

No, *really*

- Assignment ($x = x + 1$)
- Booleans, integers, characters, strings, ...
- Conditionals
- Loops
- `return`, `break`, `continue`
- Functions
- Recursion
- References / pointers
- Objects and classes
- Inheritance
- Reflection

More precisely, *only thing* you can do is:

- **Define** a function
- **Call** a function

Describing a Programming Language

- *Syntax*: what do programs look like?
- *Semantics*: what do programs mean?
 - *Operational semantics*: how do programs execute step-by-step?

Syntax: What Programs Look Like

```

e ::= x           -- variable 'x'
   | (\x -> e)   -- function that takes a parameter 'x' and returns 'e'
   | (e1 e2)     -- call (function) 'e1' with argument 'e2'

```

Programs are **expressions** e (also called λ -terms) of one of three kinds:

- **Variable**
 - x, y, z
- **Abstraction** (aka *nameless function definition*)
 - $(\lambda x \rightarrow e)$
 - x is the *formal* parameter, e is the *body*
 - “for any x compute e ”
- **Application** (aka *function call*)
 - $(e1\ e2)$
 - $e1$ is the *function*, $e2$ is the *argument*
 - in your favorite language: $e1(e2)$

(Here each of $e, e1, e2$ can itself be a variable, abstraction, or application)

- OO-lambda
- ieng6.
 - 'cs130wi21'
 - rm -rf ~/stark-wrk
 - looks like
 - $e ::= x, y, z, \dots$
 - | $(\lambda x \rightarrow e)$
 - | $(\underline{e}_1\ \underline{e}_2)$

Examples

$(\lambda x \rightarrow x)$ -- The identity function (id) that returns its input

$(\lambda x \rightarrow (\lambda y \rightarrow y))$ -- A function that returns (id)

$(\lambda f \rightarrow (f (\lambda x \rightarrow x)))$ -- A function that applies its argument to id

QUIZ

Which of the following terms are syntactically **incorrect**?

A. $(\lambda (\lambda x \rightarrow x) \rightarrow y)$
not a variable

B. $(\lambda x \rightarrow (x x))$

C. $(\lambda x \rightarrow (x (y x)))$

D. A and C

E. all of the above

Examples

`(\x -> x)` -- The identity function (*id*) that returns its input

`(\x -> (\y -> y))` -- A function that returns (*id*)

`(\f -> (f (\x -> x)))` -- A function that applies its argument to *id*

func  *arg* 

How do I define a function with two arguments?

- e.g. a function that takes x and y and returns y?

(e₁ e₂)
 
func *arg*

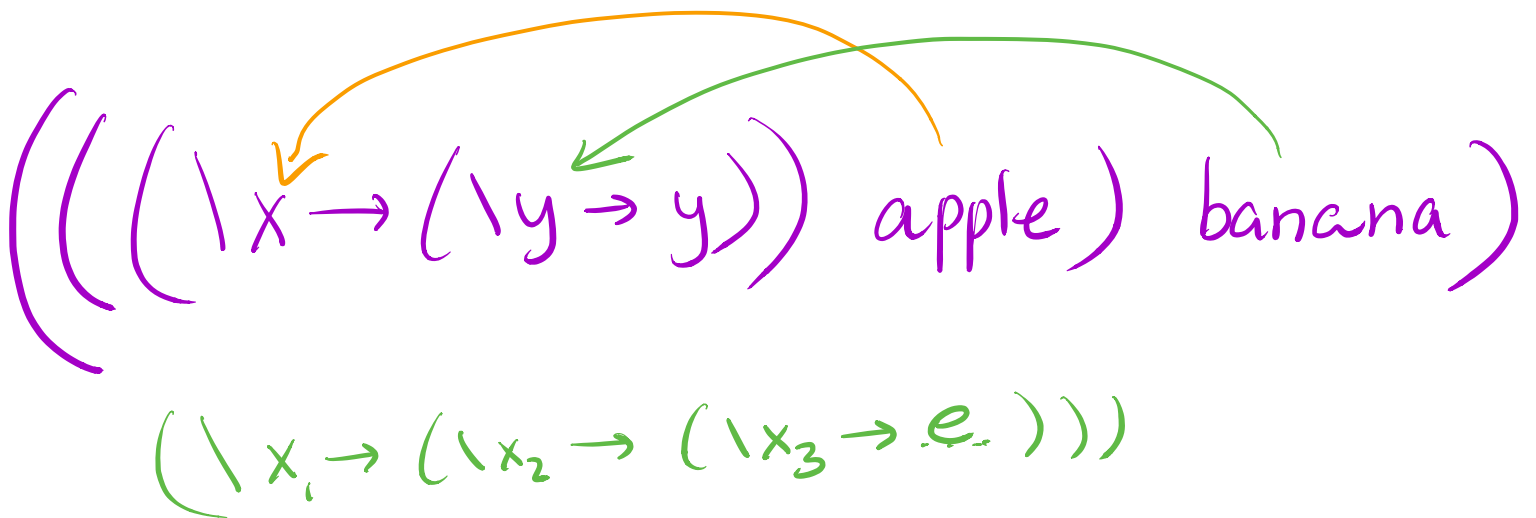

func (x, y) { return y }

(\x -> (\y -> y))

```
(\x -> (\y -> y))  -- A function that returns the identity function
on
-- OR: a function that takes two arguments
-- and returns the second one!
```

How do I apply a function to two arguments?

- e.g. apply `(\x -> (\y -> y))` to apple and banana?

$((\lambda x \rightarrow (\lambda y \rightarrow y)) \text{ apple}) \text{ banana}$ -- first apply to *apple*,
 -- then apply the result to *banana*

Syntactic Sugar

instead of

we write

instead of	we write
$\lambda x \rightarrow (\lambda y \rightarrow (\lambda z \rightarrow e))$	$\lambda x \rightarrow \lambda y \rightarrow \lambda z \rightarrow e$
$\lambda x \rightarrow \lambda y \rightarrow \lambda z \rightarrow e$	$\lambda x y z \rightarrow e$
$((e1 e2) e3) e4$	$e1 e2 e3 e4$

$\lambda x y \rightarrow y$ *-- A function that that takes two arguments
-- and returns the second one...*

$(\lambda x y \rightarrow y)$ apple banana *-- ... applied to two arguments*

Syntax "look like"

Semantic "mean"

Semantics : What Programs Mean

How do I "run" / "execute" a λ -term?

Think of middle-school algebra:

$$\begin{aligned}
 & (1 + 2) * ((3 * 8) - 2) \\
 = & 3 * ((3 * 8) - 2) \\
 = & 3 * (24 - 2) \\
 = & 3 * 22 \\
 = & 66
 \end{aligned}$$

e
 \downarrow
 e_1
 \downarrow
 e_2
 \downarrow
 \vdots
 \downarrow
 66
 "result"

Execute = rewrite step-by-step

- Following simple *rules*
- until no more rules apply

Rewrite Rules of Lambda Calculus

1. β -step (aka function call)
2. α -step (aka renaming formals)

Programming
"Scope"

But first we have to talk about scope

```

{ var x = "cat"
  { var x = "dog"
    // x is "dog"
  }
  // x is "cat"
}

```

Diagram illustrating variable scope with curly braces and arrows. A blue arrow points from the word "scope" in the text above to the inner brace. A green arrow points from the word "x" in the text to the inner brace. A green arrow points from the word "x" in the text to the outer brace.

Semantics: Scope of a Variable

The part of a program where a variable is visible

In the expression $(\lambda x \rightarrow e)$

$\text{func}(x) \{ \text{return } e \}$

- x is the newly introduced variable
- e is **the scope** of x
- any occurrence of x in $(\lambda x \rightarrow e)$ is **bound** (by the **binder** λx)

For example, x is bound in:

$(\lambda x \rightarrow x)$

$(\lambda x \rightarrow (\lambda y \rightarrow x))$

An occurrence of x in e is **free** if it's *not bound* by an enclosing abstraction

For example, x is free in:

$(x\ y)$ -- no binders at all!

$(\lambda y \rightarrow (x\ y))$ -- no λx binder

$((\lambda x \rightarrow (\lambda y \rightarrow y))\ x)$ -- x is outside the scope of the λx binder

-- intuition: it's not "the same" x

QUIZ

Is x *bound* or *free* in the expression $((\lambda x \rightarrow x)\ x)$?

A. first occurrence is bound, second is bound

B. first occurrence is bound, second is free

C. first occurrence is free, second is bound

D. first occurrence is free, second is free

EXERCISE: Free Variables

An variable x is free in e if there exists a free occurrence of x in e

We can formally define the set of *all free variables* in a term like so:

$$\begin{aligned}
 FV(x) &= \{x\} & FV(\lambda x. e) &= \{e\} \\
 FV(\lambda x. e) &= \{e\} & FV(e_1 e_2) &= \{e_1, e_2\} \\
 FV(e_1 e_2) &= \{e_1, e_2\} & FV(\lambda x. \lambda y. e) &= \{e\} \\
 & & FV(\lambda x. \lambda y. e) &= \{e\}
 \end{aligned}$$

Handwritten examples:

- $FV(\lambda x. e) = \{e\}$ (with x above e)
- $FV(\text{apple banana}) = \{\text{apple, banana}\}$
- $FV(\lambda \text{apple} \rightarrow \text{apple}) = \{\}$ (with arrow from apple to apple)
- $FV(\lambda \text{apple} \rightarrow \text{banana}) = \{\text{banana}\}$ (with banana underlined)

$$FV(x) = \{x\}$$

$$FV(\lambda x.e) = FV(e) - x$$

$$FV(e_1 e_2) = FV(e_1) + FV(e_2)$$

↑
func

Closed Expressions

If e has no free variables it is said to be **closed**

- Closed expressions are also called combinators

What is the shortest closed expression?

$$\lambda x.x$$

Rewrite Rules of Lambda Calculus

1. β -step (aka function call)
2. α -step (aka renaming formals)

Semantics: Redex

A redex is a term of the form

$$((\lambda x \rightarrow e1) \ e2)$$

$\underbrace{\hspace{2em}}_{\text{func}}$
 $\underbrace{\hspace{2em}}_{\text{arg}}$

A function $(\lambda x \rightarrow e1)$

- x is the parameter
- $e1$ is the returned expression

Applied to an argument $e2$

- $e2$ is the argument

Semantics: β -Reduction

A redex β -steps to another term ...

$$(\lambda x \rightarrow e1) e2 \quad \beta \rightarrow \quad e1[x := e2]$$

where $e1[x := e2]$ means

“ $e1$ with all *free* occurrences of x replaced with $e2$ ”

$$(\lambda x \rightarrow x) \text{ apple} \quad \beta \rightarrow \quad \text{apple}$$

Computation by search-and-replace:

If you see an abstraction applied to an *argument*,

- In the *body* of the abstraction
- Replace all *free occurrences* of the *formal* by that *argument*

We say that $(\lambda x \rightarrow e_1) e_2$ β -steps to $e_1[x := e_2]$

$$(\lambda x \rightarrow e_1) e_2 \Rightarrow e_1[x := e_2]$$

Redex Examples

$((\lambda x \rightarrow x) \text{ apple})$

$\Rightarrow \text{apple}$

Is this right? Ask Elsa (<https://goto.ucsd.edu/elsa/index.html>)

QUIZ

- B. (apple (λ apple \rightarrow apple))
- C. (apple ($\lambda x \rightarrow$ apple))
- D. apple
- E. ($\lambda x \rightarrow x$)

$(\lambda x \rightarrow (x (\lambda x \rightarrow x)))$
 def (binder)
 func (x) Σ
 return $x+1$ use (occurrences)

$(1+2)+3$
 $= 3+3$
 $= 6$

$(\lambda x \rightarrow \boxed{e_1}) e_2$

EXERCISE

What is a λ -term fill_this_in such that

fill_this_in apple
 =b> banana

$(\dots \text{apple})$
 $=b> \text{banana}$

ELSA: <https://goto.ucsd.edu/elsa/index.html>

Click here to try this exercise (https://goto.ucsd.edu/elsa/index.html#?demo=permalink%2F1585434473_24432.lc)

$(\lambda x \rightarrow ?) \text{ apple} = b \rightarrow \underline{\text{banana}} \quad \times$

$? [x := \text{apple}] \equiv \underline{\text{banana}}$
 banana

A Tricky One $\$ \text{ make}$

"downloading GHC"

$((\lambda x \rightarrow (\lambda y \rightarrow x)) y)$

(1) Make sure your $\$ \text{ PATH}$
 is set (cs131w)

$= b \rightarrow \lambda y \rightarrow y$

(2) $\text{rm -rf } \sim / . \text{stack}$

Is this right?

SYNTAX

$e ::= x, y, z$ \rightarrow formal
 $(\lambda x \rightarrow e)$ \rightarrow body
 (e_1, e_2) \rightarrow "arg"
 \rightarrow "function"

$(\lambda x \rightarrow e_1) e_2$

REDEX

formal body arg

$((\lambda x \rightarrow (x x)) \text{ apple})$

$= b \rightarrow (\text{apple apple})$

Something is Fishy

Is this right?

Problem: The *free* y in the argument has been **captured** by λy in *body*!

Solution: Ensure that *formals* in the body are **different from free-variables** of argument!

Capture-Avoiding Substitution

We have to fix our definition of β -reduction:

$$(\lambda x \rightarrow e_1) e_2 \quad =_{\beta} \quad e_1[x := e_2]$$

where $e_1[x := e_2]$ means “ ~~e_1 with all free occurrences of x replaced with e_2~~ ”

- e_1 with all *free* occurrences of x replaced with e_2
- **as long as** no free variables of e_2 get captured

Formally:

$$x[x := e] \quad = \quad e$$

$$y[x := e] \quad = \quad y \quad \text{-- as } x \neq y$$

$$(e_1 e_2)[x := e] \quad = \quad (e_1[x := e]) (e_2[x := e])$$

$$(\lambda x \rightarrow e_1)[x := e] \quad = \quad (\lambda x \rightarrow e_1) \quad \text{-- Q: Why leave `e1` unchanged?}$$

$$\begin{aligned} &(\lambda y \rightarrow e_1)[x := e] \\ & \quad | \text{ not } (y \text{ in } \text{FV}(e)) = \lambda y \rightarrow e_1[x := e] \end{aligned}$$

Oops, but what to do if y is in the free-variables of e ?

- i.e. if $\lambda y \rightarrow \dots$ may *capture* those free variables?

Rewrite Rules of Lambda Calculus

1. β -step (aka function call)
2. α -step (aka renaming formals)

function (x) {
 return $x+1$;
}

function (y) {
 return $y+1$;
}

function (z) {
 return $z+1$;
}

Semantics: α -Renaming

$\lambda x \rightarrow y \quad \neq \lambda y \rightarrow y$

$\lambda x \rightarrow e \quad \text{=a>} \quad \lambda y \rightarrow e[x := y]$
 where not (y in FV(e))

$\lambda x \rightarrow x \quad \text{=a>} \quad \lambda y \rightarrow y \quad \text{=a>} \quad \lambda z \rightarrow z$

- We rename a formal parameter x to y
- By replace all occurrences of x in the body with y
- We say that $\lambda x \rightarrow e$ α -steps to $\lambda y \rightarrow e[x := y]$

Example:

$(\lambda x \rightarrow x) \quad \text{=a>} \quad (\lambda y \rightarrow y) \quad \text{=a>} \quad (\lambda z \rightarrow z)$

All these expressions are α -equivalent

What's wrong with these?

-- (A)

$(\lambda f \rightarrow (f \ x)) \quad \text{=a>} \quad (\lambda x \rightarrow (x \ x))$

-- (B)

$((\lambda x \rightarrow (\lambda y \rightarrow y)) \ y) \quad \text{=a>} \quad ((\lambda x \rightarrow (\lambda z \rightarrow z)) \ z)$

outside scope of binder

Tricky Example Revisited

```
((\x -> (\y -> x)) y)
```

-- rename 'y' to 'z' to avoid capture

ure

```
=a> ((\x -> (\z -> x)) y)
```

-- now do b-step without capture!

```
=b> (\z -> y)
```

To avoid getting confused,

- you can **always rename** formals,
- so different **variables** have different **names!**

Normal Forms

Recall **redex** is a λ -term of the form

$((\lambda x \rightarrow e1) e2)$

A λ -term is in **normal form** if it contains no redexes.

$(\lambda x \rightarrow y)$

QUIZ

Which of the following term are **not** in normal form?

A. x

no-redex

ie contain further β -steps?
 β -redexes?

B. $(x\ y)$ *no-redex*

✓ C. $((\lambda x \rightarrow x)\ y)$

yes-redex

D. $(x\ (\lambda y \rightarrow y))$

no-redex

E. C and D

$((\lambda x \rightarrow e_1)\ e_2)$

↑
left
(func)

↑
right
(arg)

Semantics: Evaluation

A λ -term e evaluates to e' if

1. There is a sequence of steps

$e \Rightarrow e_1 \Rightarrow \dots \Rightarrow e_N \Rightarrow e'$

where each \Rightarrow is either $=a>$ or $=b>$ and $N \geq 0$

2. e' is in *normal form*

$(2+2) - 3$

\parallel

$4 - 3$

\parallel

1

(normal)

Examples of Evaluation

$(\lambda x \rightarrow x)$ apple

=b> apple

$(\lambda f \rightarrow f (\lambda x \rightarrow x)) (\lambda x \rightarrow x)$

=?> ???

$(\lambda x \rightarrow x x) (\lambda x \rightarrow x)$

=?> ???

Elsa shortcuts

Named λ -terms:

let ID = $(\lambda x \rightarrow x)$ -- abbreviation for $(\lambda x \rightarrow x)$

To substitute name with its definition, use a $=d>$ step:

(ID apple)

$=d> ((\lambda x \rightarrow x) \text{ apple})$ -- *expand definition*

$=b> \text{ apple}$ -- *beta-reduce*

Evaluation:

- $e1 =*> e2$: $e1$ reduces to $e2$ in 0 or more steps
 - where each step is $=a>$, $=b>$, or $=d>$
- $e1 =\sim> e2$: $e1$ evaluates to $e2$ and $e2$ is in normal form

$$(\lambda x \rightarrow x x) (\lambda y \rightarrow y y)$$

$$=b> (\lambda y \rightarrow y y) (\lambda y \rightarrow y y)$$

EXERCISE

Fill in the definitions of FIRST, SECOND and THIRD such that you get the

following behavior in elsa

```
let FIRST = fill_this_in ( \x -> x)
let SECOND = fill_this_in
let THIRD = fill_this_in
```

```
eval ex1 :
(((FIRST apple) banana) orange)
=> apple
```

Handwritten annotations: Red curly braces group the arguments in the lambda expression. The word 'apple' is written in red above the result.

```
eval ex2 :
(((SECOND apple) banana) orange)
=> banana
```

Handwritten annotations: A lambda expression $(\lambda x_1 \rightarrow (\lambda x_2 \rightarrow (\lambda x_3 \rightarrow x_1)))$ is written in red. The variables x_1 , x_2 , and x_3 are circled in orange, yellow, and green respectively. The words 'apple', 'banana', and 'orange' are written in red below the lambda expression, with 'apple' circled in orange, 'banana' in yellow, and 'orange' in green.

```
eval ex3 :
(((THIRD apple) banana) orange)
=> orange
```

ELSA: <https://goto.ucsd.edu/elsa/index.html>

Click here to try this exercise (https://goto.ucsd.edu/elsa/index.html#?demo=permalink%2F1585434130_24421.lc)

Non-Terminating Evaluation

```
((\x -> (x x)) (\x -> (x x)))
```

```
=b> ((\x -> (x x)) (\x -> (x x)))
```

Some programs loop back to themselves ... *never* reduce to a normal form!

This combinator is called Ω

What if we pass Ω as an argument to another function?

```
let OMEGA = ((\x -> (x x)) (\x -> (x x)))
```

```
((\x -> (\y -> y)) OMEGA)
```

Does this reduce to a normal form? Try it at home!

Programming in λ -calculus

Real languages have lots of features

- Booleans $\rightarrow \tau, f, \text{if-then-else}, \& \text{b}, \ll$
- Records (structs, tuples) $\rightarrow \{ \text{fst} : - , \text{snd} : - \}$
- Numbers $\rightarrow 2 + 5$ *lists, trees* $\{ x : - , y : - , z : - \}$

✓ Functions [we got those]

- Recursion

Lets see how to *encode* all of these features with the λ -calculus.

Syntactic Sugar

instead of	we write
$\lambda x \rightarrow (\lambda y \rightarrow (\lambda z \rightarrow e))$	$\lambda x \rightarrow \lambda y \rightarrow \lambda z \rightarrow e$
$\lambda x \rightarrow \lambda y \rightarrow \lambda z \rightarrow e$	$\lambda x y z \rightarrow e$
$((e1 e2) e3) e4$	$e1 e2 e3 e4$

$\lambda x y \rightarrow y$ *-- A function that that takes two arguments
-- and returns the second one...*

$(\lambda x y \rightarrow y)$ apple banana *-- ... applied to two arguments*

λ -calculus: Booleans

bool/cond?
↙ TRUE ↘ FALSE
res-true res-false

How can we encode Boolean values (TRUE and FALSE) as functions?

Well, what do we **do** with a Boolean b ?

decisions / condition / choice

Make a *binary choice*

• `if b then e1 else e2`

$b ? e_1 : e_2$

Booleans: API

We need to define three functions

`let TRUE = ???` $(\lambda x \rightarrow (\lambda y \rightarrow x))$
`let FALSE = ???` $(\lambda x \rightarrow (\lambda y \rightarrow y))$
`let ITE = $\lambda b \lambda x \lambda y \rightarrow$???` -- if b then x else y
 $(b \ x \ y)$

such that

ITE TRUE apple banana \rightsquigarrow apple

ITE FALSE apple banana \rightsquigarrow banana

(Here, `let NAME = e` means NAME is an *abbreviation* for e)

Booleans: Implementation

```

let TRUE  = \x y -> x      -- Returns its first argument
let FALSE = \x y -> y      -- Returns its second argument
let ITE    = \b x y -> b x y -- Applies condition to branches
                                     -- (redundant, but improves readability)

```

Example: Branches step-by-step

```

eval ite_true:
  ITE TRUE e1 e2
=d> (\b x y -> b x y) TRUE e1 e2  -- expand def ITE
=b>  (\x y -> TRUE x y) e1 e2     -- beta-step
=b>  (\y -> TRUE e1 y) e2        -- beta-step
=b>  TRUE e1 e2                  -- expand def TRUE
=d>  (\x y -> x) e1 e2           -- beta-step
=b>  (\y -> e1) e2              -- beta-step
=b>  e1

```

Example: Branches step-by-step

Now you try it!

Can you fill in the blanks to make it happen? (<http://goto.ucsd.edu:8095/index.html#?demo=ite.lc>)

```
eval ite_false:
```

```
  ITE FALSE e1 e2
```

```
-- fill the steps in!
```

```
=b> e2
```

EXERCISE: Boolean Operators

ELSA: <https://goto.ucsd.edu/elsa/index.html> Click here to try this exercise
(https://goto.ucsd.edu/elsa/index.html#?demo=permalink%2F1585435168_24442.lc)

Now that we have ITE it's easy to define other Boolean operators:

```
[ let NOT = \b      -> ???  
  let OR  = \b1 b2 -> ???  
  let AND = \b1 b2 -> ???
```

When you are done, you should get the following behavior:

eval ex_not_t:

NOT TRUE => FALSE

eval ex_not_f:

NOT FALSE => TRUE

eval ex_or_ff:

OR FALSE FALSE => FALSE

eval ex_or_ft:

OR FALSE TRUE => TRUE

eval ex_or_ft:

OR TRUE FALSE => TRUE

eval ex_or_tt:

OR TRUE TRUE => TRUE

eval ex_and_ff:

AND FALSE FALSE => FALSE

eval ex_and_ft:

AND FALSE TRUE => FALSE

eval ex_and_ft:

AND TRUE FALSE => FALSE

eval ex_and_tt:

AND TRUE TRUE => TRUE

AND TT FF \leadsto FF
 AND FF FF \leadsto FF
 AND FF TT \leadsto FF
 AND TT TT \leadsto TT

OO-lambda deadline \Rightarrow 1/17 23:59P

Programming in λ -calculus

- ✓ • Booleans [done]
- Records (structs, tuples)
- Numbers
- USTS
- Functions [we got those]
- Recursion ← NOT NEEDED for OO-lambda

\Rightarrow apple
SND \Rightarrow banana

λ -calculus: Records

Let's start with records with *two* fields (aka **pairs**)

What do we *do* with a pair?

1. Pack two items into a pair, then
2. Get first item, or
3. Get second item.

ITE ? x y
"index"

Pairs : API

We need to define three functions

```

let PAIR = \x y -> ???    -- Make a pair with elements x and y
                        -- { fst : x, snd : y }
let FST  = \p -> ???     -- Return first element
                        -- p.fst
let SND  = \p -> ???     -- Return second element
                        -- p.snd

```

Handwritten annotations: A small box containing 'x' and 'y' is positioned above the 'PAIR' function definition. An orange arrow points from this box to the 'x' and 'y' arguments in the lambda expression. Below the 'FST' function definition, the letter 'x' is written in orange. Below the 'SND' function definition, the letter 'y' is written in orange.

such that

eval ex_fst:

FST (PAIR apple banana) ==> apple

eval ex_snd:

SND (PAIR apple banana) ==> banana

let PAIR = $\lambda x y \rightarrow (\lambda b \rightarrow \text{ITE } b \ x \ y)$

let FST = $\lambda t \rightarrow t \text{ TRUE}$

let SND = $\lambda t \rightarrow t \text{ FALSE}$

Pairs: Implementation

A pair of x and y is just something that lets you pick between x and y ! (i.e. a function that takes a boolean and returns either x or y)

let PAIR = $\lambda x y \rightarrow (\lambda b \rightarrow \text{ITE } b \ x \ y)$

let FST = $\lambda p \rightarrow p \text{ TRUE}$ -- call w/ TRUE, get first value

let SND = $\lambda p \rightarrow p \text{ FALSE}$ -- call w/ FALSE, get second value

EXERCISE: Triples

How can we implement a record that contains three values?

ELSA: <https://goto.ucsd.edu/elsa/index.html>

Click here to try this exercise (https://goto.ucsd.edu/elsa/index.html#?demo=permalink%2F1585434814_24436.lc)

let TRIPLE = \x y z -> ???

let FST3 = \t -> ???

let SND3 = \t -> ???

let THD3 = \t -> ???

eval ex1:

FST3 (TRIPLE apple banana orange)

=*> apple

eval ex2:

SND3 (TRIPLE apple banana orange)

=*> banana

eval ex3:

THD3 (TRIPLE apple banana orange)

=*> orange

TRIP PAIR (PAIR app ban) orange

TRIPLE x y z ≡ PAIR (PAIR x y) z

Programming in λ -calculus

COMPARISONS

λ -calculus: Numbers

Let's start with **natural numbers** (0, 1, 2, ...)

What do we do with natural numbers?

- Count: 0, inc
- Arithmetic: dec, +, -, *
- Comparisons: ==, <=, etc

"three"

$\lambda f \rightarrow \lambda x \rightarrow f(f(f x))$

"four"

$\lambda f x \rightarrow f(f(f(f x)))$

⋮

Natural Numbers: API

We need to define:

- A family of **numerals**: ZERO , ONE , TWO , THREE , ...
- Arithmetic functions: INC , DEC , ADD , SUB , MULT
- Comparisons: IS_ZERO , EQ

Such that they respect all regular laws of arithmetic, e.g.

```
IS_ZERO ZERO          ==> TRUE
IS_ZERO (INC ZERO) ==> FALSE
INC ONE              ==> TWO
...
```

Natural Numbers: Implementation

Church numerals: a number N is encoded as a combinator that calls a function on an argument N times

let ONE = $\lambda f x \rightarrow f x$

let TWO = $\lambda f x \rightarrow f (f x)$

let THREE = $\lambda f x \rightarrow f (f (f x))$

let FOUR = $\lambda f x \rightarrow f (f (f (f x)))$

let FIVE = $\lambda f x \rightarrow f (f (f (f (f x))))$

let SIX = $\lambda f x \rightarrow f (f (f (f (f (f x))))))$

...

"N" = $\lambda f x \rightarrow f (\dots (f x))$
 "N" times

(TWO $f x$) $\Rightarrow f (f x)$

(THREE $f x$) $\Rightarrow f (f (f x))$

$r = x$
 for i in $1..n$:
 $r = f(r)$

(N $f x$) $\Rightarrow f (f (f \dots f (x)))$
 "N" times

QUIZ: Church Numerals

Which of these is a valid encoding of ZERO ?

• A: `let ZERO = \f x -> x` ✓ "zero" times

• B: `let ZERO = \f x -> f`

• C: `let ZERO = \f x -> f x` ONE

• D: `let ZERO = \x -> x` "does not take 'func' as arg"

• E: None of the above

(x)

Does this function look familiar?

λ-calculus: Increment

$n \ f \ ONE$

$=* (f \dots (f (f \ ONE)))$
 $\underbrace{\hspace{10em}}_n$

-- Call 'f' on 'x' one more time than 'n' does

`let INC = \n -> (\f x -> ???)`
 number num

call 'f' on 'x' N-times

$\lambda n \rightarrow (\lambda f x \rightarrow f(n \ f \ x))$ one more time

$\lambda n \rightarrow (\lambda f x \rightarrow n \ f \ (f \ x))$

$INC\ ZERO \Rightarrow ONE$
 $INC\ ONE \Rightarrow TWO$
 $INC\ SIX \Rightarrow SEVEN$

Example:

eval inc_zero :

INC ZERO

=d> (\n f x -> f (n f x)) ZERO

=b> \f x -> f (ZERO f x)

=*> \f x -> f x

=d> ONE

EXERCISE

Fill in the implementation of `ADD` so that you get the following behavior

Click here to try this exercise (<https://goto.ucsd.edu>

[/elsa/index.html#?demo=permalink%2F1585436042_24449.lc](https://goto.ucsd.edu/elsa/index.html#?demo=permalink%2F1585436042_24449.lc))

```
let ZERO = \f x -> x
let ONE  = \f x -> f x
let TWO  = \f x -> f (f x)
let INC  = \n f x -> f (n f x)
```

```
let ADD = fill_this_in
```

```
eval add_zero_zero:
```

```
ADD ZERO ZERO ==> ZERO
```

```
eval add_zero_one:
```

```
ADD ZERO ONE ==> ONE
```

```
eval add_zero_two:
```

```
ADD ZERO TWO ==> TWO
```

```
eval add_one_zero:
```

```
ADD ONE ZERO ==> ONE
```

```
eval add_one_one:
```

```
ADD ONE ONE ==> TWO
```

```
eval add_two_zero:
```

```
ADD TWO ZERO ==> TWO
```

QUIZ

let ADD = $\lambda n m \rightarrow$?
 NUMBER

How shall we implement ADD?

- A. let ADD = $\lambda n m \rightarrow n \text{ INC } m$?
 $m \text{ INC } n$
- B. let ADD = $\lambda n m \rightarrow \text{INC } n \ m$?
 $(\text{INC} \dots (\text{INC} (\text{INC } m)))$
 N-times
- C. let ADD = $\lambda n m \rightarrow n \ m \text{ INC}$
- D. let ADD = $\lambda n m \rightarrow n (m \text{ INC})$
- E. let ADD = $\lambda n m \rightarrow n \text{ (INC } m)$

λ -calculus: Addition

-- Call `f` on `x` exactly `n + m` times

let ADD = $\lambda n m \rightarrow n \text{ INC } m$

Example:

```
eval add_one_zero :
  ADD ONE ZERO
  => ONE
```

QUIZ

How shall we implement MULT ?

A. **let** MULT = \n m -> n ADD m *x no! add takes 2*

B. **let** MULT = \n m -> n (ADD m) ZERO

C. **let** MULT = \n m -> m (ADD n) ZERO

D. **let** MULT = \n m -> n (ADD^m ZERO) *x (n m -> n m)*

E. **let** MULT = \n m -> (n ADD m) ZERO *x n * m*

(ADD_m . (ADD_m (ADD_m (ADD_m ZERO)))
(n + (n + (n + 0)))

$$\text{MUL } n \ m = n \ (\text{ADD } m) \ 0$$

$$n \ f \ x = \underbrace{f \dots (f \ (f \ x))}_n$$

$$\underbrace{((\text{ADD } m) \dots ((\text{ADD } m) (\text{ADD } m) ((\text{ADD } m) \ 0)))}_{n \text{-times}}$$

λ -calculus: Multiplication

-- Call `f` on `x` exactly `n * m` times

```
let MULT = \n m -> n (ADD m) ZERO
```

Example:

```
eval two_times_three :
```

```
MULT TWO ONE
```

```
=~> TWO
```

$$\boxed{\text{ADD3}} = \lambda n \rightarrow \text{INL}(\text{INL}(\text{INC } n))$$

$$\boxed{\text{ADD_THREE}}$$

Programming in λ -calculus

- Booleans [done]
- Records (structs, tuples) [done]
- Numbers [done] minus
- Lists
- Functions [we got those]
- Recursion

$$\underline{\text{ISZERO}} = \lambda n \rightarrow \begin{cases} \text{TRUE} & \text{if } n = \text{ZERO} \\ \text{FALSE} & \text{o.w.} \end{cases}$$

$$\lambda n \rightarrow (n \text{ ? } f \text{ ? } x) = \text{TRUE}$$

\parallel "TRUE" = FALSE
 (1z → FALSE)

$$\lambda n \rightarrow n \text{ (1z → FALSE) TRUE}$$

only called when $n \neq 0$

λ -calculus: Lists

Lets define an API to build lists in the λ -calculus.

An Empty List

PAIR

TRIPLE

NIL = ZERO

$CONS\ h\ t = (PAIR\ \overset{fst}{h}\ \overset{snd}{t})$
 NIL = ZERO

Constructing a list

A list with 4 elements

- head h
- tail t

[cantaloupe, dragon]

[banana, cantaloupe, dragon]

Destructing a list

[apple, banana, cantaloupe, dragon]

- HEAD l returns the first element of the list
- TAIL l returns the rest of the list

HEAD = l → FST e

TAIL = l → SND e

```
HEAD (CONS apple (CONS banana (CONS cantaloupe (CONS dragon NIL))))
=> apple
```

```
TAIL (CONS apple (CONS banana (CONS cantaloupe (CONS dragon NIL))))
=> CONS banana (CONS cantaloupe (CONS dragon NIL))
```

λ -calculus: Lists

```
let NIL = ???
```

```
let CONS = ???
```

```
let HEAD = ???
```

```
let TAIL = ???
```

```
eval exHd:
```

```
  HEAD (CONS apple (CONS banana (CONS cantaloupe (CONS dragon NI  
L))))
```

```
  =~> apple
```

```
eval exTl
```

```
  TAIL (CONS apple (CONS banana (CONS cantaloupe (CONS dragon NI  
L))))
```

```
  =~> CONS banana (CONS cantaloupe (CONS dragon NIL))
```

EXERCISE: Nth

Write an implementation of `GetNth` such that

- `GetNth n l` returns the n -th element of the list l

Assume that l has n or more elements

let `GetNth` = ???

eval `nth1` :

`GetNth ZERO (CONS apple (CONS banana (CONS cantaloupe NIL)))`
 \rightsquigarrow apple

head $\ln l \rightarrow \text{HEAD } (n \text{ TAIL } l)$

eval `nth1` :

`GetNth ONE (CONS apple (CONS banana (CONS cantaloupe NIL)))`
 \rightsquigarrow banana

tail *head*

eval `nth2` :

`GetNth TWO (CONS apple (CONS banana (CONS cantaloupe NIL)))`
 \rightsquigarrow cantaloupe

tail *tail* *head*

Click here to try this in elsa (<https://goto.ucsd.edu>

[/elsa/index.html#?demo=permalink%2F1586466816_52273.lc](https://goto.ucsd.edu/elsa/index.html#?demo=permalink%2F1586466816_52273.lc))

 λ -calculus: Recursion

I want to write a function that sums up natural numbers up to n :

```
let SUM = \n -> ... -- 0 + 1 + 2 + ... + n
```

such that we get the following behavior

```
eval exSum0: SUM ZERO ==> ZERO
```

```
eval exSum1: SUM ONE ==> ONE
```

```
eval exSum2: SUM TWO ==> THREE
```

```
eval exSum3: SUM THREE ==> SIX
```

Can we write sum **using Church Numerals**?

Click here to try this in Elsa (https://goto.ucsd.edu/elsa/index.html#?demo=permalink%2F1586465192_52175.lc)

QUIZ

You *can* write SUM using numerals but its *tedious*.

Is this a correct implementation of SUM?

```
let SUM = \n -> ITE (ISZ n)
                ZERO
                (ADD n (SUM (DEC n)))
```

A. Yes

B. No

No!

- Named terms in Elsa are just syntactic sugar
- To translate an Elsa term to λ -calculus: replace each name with its definition

```
\n -> ITE (ISZ n)
          ZERO
          (ADD n (SUM (DEC n))) -- But SUM is not yet defined!
```

Recursion:

- Inside *this* function
- Want to call the *same* function on `DEC n`

Looks like we can't do recursion!

- Requires being able to refer to functions *by name*,
- But λ -calculus functions are *anonymous*.

Right?

λ -calculus: Recursion

Think again!

Recursion:

Instead of

- Inside *this* function I want to call the *same* function on $\text{DEC } n$

Lets try

- Inside *this* function I want to call *some* function `rec` on $\text{DEC } n$
- And BTW, I want `rec` to be the *same* function

Step 1: Pass in the function to call “recursively”

```
let STEP =
  \rec -> \n -> ITE (ISZ n)
                    ZERO
                    (ADD n (rec (DEC n))) -- Call some rec
```

Step 2: Do some magic to `STEP`, so `rec` is itself

```
\n -> ITE (ISZ n) ZERO (ADD n (rec (DEC n)))
```

That is, obtain a term `MAGIC` such that

```
MAGIC => STEP MAGIC
```

λ -calculus: Fixpoint Combinator

Wanted: a λ -term FIX such that

- FIX STEP calls STEP with FIX STEP as the first argument:

$(\text{FIX STEP}) \Rightarrow \text{STEP (FIX STEP)}$

(In math: a *fixpoint* of a function $f(x)$ is a point x , such that $f(x) = x$)

Once we have it, we can define:

let SUM = FIX STEP

Then by property of FIX we have:

SUM \Rightarrow FIX STEP \Rightarrow STEP (FIX STEP) \Rightarrow STEP SUM

and so now we compute:

```
eval sum_two:
```

```

SUM TWO
=> STEP SUM TWO
=> ITE (ISZ TWO) ZERO (ADD TWO (SUM (DEC TWO)))
=> ADD TWO (SUM (DEC TWO))
=> ADD TWO (SUM ONE)
=> ADD TWO (STEP SUM ONE)
=> ADD TWO (ITE (ISZ ONE) ZERO (ADD ONE (SUM (DEC ONE))))
=> ADD TWO (ADD ONE (SUM (DEC ONE)))
=> ADD TWO (ADD ONE (SUM ZERO))
=> ADD TWO (ADD ONE (ITE (ISZ ZERO) ZERO (ADD ZERO (SUM DEC ZER
0))))
=> ADD TWO (ADD ONE (ZERO))
=> THREE

```

How should we define FIX ???

The Y combinator

Remember Ω ?

```
(\x -> x x) (\x -> x x)
=b> (\x -> x x) (\x -> x x)
```

This is *self-replicating code*! We need something like this but a bit more involved...

The Y combinator discovered by Haskell Curry:

```
let FIX = \stp -> (\x -> stp (x x)) (\x -> stp (x x))
```

How does it work?

```
eval fix_step:
```

```
FIX STEP
=d> (\stp -> (\x -> stp (x x)) (\x -> stp (x x))) STEP
=b> (\x -> STEP (x x)) (\x -> STEP (x x))
=b> STEP ((\x -> STEP (x x)) (\x -> STEP (x x)))
--      ^^^^^^^^^^^^^ this is FIX STEP ^^^^^^^^^^^^^
```

That's all folks, Haskell Curry was very clever.

Next week: We'll look at the language named after him (Haskell)
