

Lambda Calculus

Your Favorite Language

Probably has lots of features:

- Assignment ($x = x + 1$)
- Booleans, integers, characters, strings, ...
- Conditionals
- Loops
- `return`, `break`, `continue`
- Functions
- Recursion
- References / pointers
- Objects and classes
- Inheritance
- ...

Which ones can we do without?

What is the **smallest universal language**?

What is computable?

Before 1930s

Informal notion of an **effectively calculable function**:

can be computed by a human with pen and paper, following an algorithm

1936: Formalization

What is the **smallest universal language**?

Alan Turing

Alonzo Church

The Next 700 Languages

Peter Landin

Whatever the next 700 languages turn out to be, they will surely be variants of lambda calculus.

Peter Landin, 1966

The Lambda Calculus

Has one feature:

- Functions

No, really

- ~~Assignment ($x = x + 1$)~~
- ~~Booleans, integers, characters, strings, ...~~
- ~~Conditionals~~
- ~~Loops~~
- ~~`return`, `break`, `continue`~~
- ~~Functions~~
- ~~Recursion~~
- ~~References / pointers~~
- ~~Objects and classes~~
- ~~Inheritance~~
- ~~Reflection~~

More precisely, *only thing* you can do is:

- Define a function
- Call a function

Describing a Programming Language

- Syntax: what do programs look like?
- Semantics: what do programs mean?
 - *Operational semantics*: how do programs execute step-by-step?

Syntax: What Programs Look Like

```
e ::= x           -- variable 'x'
    | (\x -> e)  -- function that takes a parameter 'x' and returns 'e'
    | (e1 e2)    -- call (function) 'e1' with argument 'e2'
```

Programs are **expressions e** (also called *λ -terms*) of one of three kinds:

- **Variable**
 - x, y, z
- **Abstraction** (aka *nameless function definition*)
 - $(\lambda x \rightarrow e)$
 - x is the *formal* parameter, e is the *body*
 - “for any x compute e ”
- **Application** (aka *function call*)
 - $(e1\ e2)$
 - $e1$ is the *function*, $e2$ is the *argument*
 - in your favorite language: $e1(e2)$

(Here each of $e, e1, e2$ can itself be a variable, abstraction, or application)

Examples

```
(\x -> x)           -- The identity function (id) that returns its input
(\x -> (\y -> y))  -- A function that returns (id)
(\f -> (f (\x -> x))) -- A function that applies its argument to id
```

QUIZ

Which of the following terms are syntactically **incorrect**?

- $(\lambda(\lambda x \rightarrow x) \rightarrow y)$
- $(\lambda x \rightarrow (x\ x))$
- $(\lambda x \rightarrow (x\ (y\ x)))$
- A and C
- all of the above

Examples

```
(\x -> x)           -- The identity function (id) that returns its input
(\x -> (\y -> y))  -- A function that returns (id)
(\f -> (f (\x -> x))) -- A function that applies its argument to id
```

How do I define a function with two arguments?

- e.g. a function that takes x and y and returns y ?

```
(\x -> (\y -> y))  -- A function that returns the identity function
                  -- OR: a function that takes two arguments
                  -- and returns the second one!
```

How do I apply a function to two arguments?

- e.g. apply $(\lambda x \rightarrow (\lambda y \rightarrow y))$ to *apple* and *banana*?

```
(((\lambda x -> (\lambda y -> y)) apple) banana) -- first apply to apple,
                                         -- then apply the result to banana
```

Syntactic Sugar

instead of	we write
$\lambda x \rightarrow (\lambda y \rightarrow (\lambda z \rightarrow e))$	$\lambda x \rightarrow \lambda y \rightarrow \lambda z \rightarrow e$
$\lambda x \rightarrow \lambda y \rightarrow \lambda z \rightarrow e$	$\lambda x\ y\ z \rightarrow e$
$((e1\ e2)\ e3)\ e4$	$e1\ e2\ e3\ e4$

```
\x y -> y           -- A function that takes two arguments
                  -- and returns the second one...
```

```
(\x y -> y) apple banana -- ... applied to two arguments
```

Semantics : What Programs Mean

How do I “run” / “execute” a λ -term?

Think of middle-school algebra:

```
(1 + 2) * ((3 * 8) - 2)
==
3 * ((3 * 8) - 2)
==
3 * (24 - 2)
==
3 * 22
==
66
```

Execute = rewrite step-by-step

- Following simple rules
- until no more rules apply

Rewrite Rules of Lambda Calculus

1. β -step (aka *function call*)
2. α -step (aka *renaming formals*)

But first we have to talk about **scope**

Semantics: Scope of a Variable

The part of a program where a **variable is visible**

In the expression $(\lambda x \rightarrow e)$

- x is the newly introduced variable
- e is the **scope** of x
- any occurrence of x in $(\lambda x \rightarrow e)$ is **bound** (by the binder λx)

For example, x is bound in:

```
(\x -> x)
```

```
(\x -> (\y -> x))
```

An occurrence of x in e is **free** if it's *not bound* by an enclosing abstraction

For example, x is free in:

```
(x y)           -- no binders at all!
```

```
(\y -> (x y))    -- no  $\lambda x$  binder
```

```
(((\lambda x -> (\lambda y -> y)) x) --  $x$  is outside the scope of the  $\lambda x$  binder;
                          -- intuition: it's not "the same"  $x$ 
```

QUIZ

Is x *bound* or *free* in the expression $((\lambda x \rightarrow x) x)$?

- A. first occurrence is bound, second is bound
- B. first occurrence is bound, second is free
- C. first occurrence is free, second is bound
- D. first occurrence is free, second is free

EXERCISE: Free Variables

An variable x is *free* in e if *there exists* a free occurrence of x in e

We can formally define the set of all *free variables* in a term like so:

```
FV(x)      = ???
FV( $\lambda x \rightarrow e$ ) = ???
FV( $e_1 e_2$ ) = ???
```

Closed Expressions

If e has *no free variables* it is said to be **closed**

- Closed expressions are also called **combinators**

What is the shortest closed expression?

Rewrite Rules of Lambda Calculus

1. β -step (aka *function call*)
2. α -step (aka *renaming formals*)

Semantics: Redex

A **redex** is a term of the form

```
(( $\lambda x \rightarrow e_1$ )  $e_2$ )
```

A **function** $(\lambda x \rightarrow e_1)$

- x is the *parameter*
- e_1 is the *returned expression*

Applied to an argument e_2

- e_2 is the *argument*

Semantics: β -Reduction

A **redex** b -steps to another term ...

```
( $\lambda x \rightarrow e_1$ )  $e_2$   =>   $e_1[x := e_2]$ 
```

where $e_1[x := e_2]$ means

" e_1 with all free occurrences of x replaced with e_2 "

Computation by *search-and-replace*:

If you see an abstraction applied to an argument,

- In the body of the abstraction
- Replace all *free occurrences* of the *formal* by that argument

We say that $(\lambda x \rightarrow e_1) e_2$ β -steps to $e_1[x := e_2]$

Redex Examples

```
(( $\lambda x \rightarrow x$ ) apple)
```

=> apple

Is this right? Ask [Elsa](#)

QUIZ

```
(( $\lambda x \rightarrow (\lambda y \rightarrow y)$ ) apple)
```

=> ???

- A. apple
- B. $\lambda y \rightarrow$ apple
- C. $\lambda x \rightarrow$ apple
- D. $\lambda y \rightarrow y$
- E. $\lambda x \rightarrow y$

QUIZ

```
( $\lambda x \rightarrow ((\lambda y x) y) x$ ) apple
```

=> ???

- A. $((\text{apple apple}) \text{apple}) \text{apple}$
- B. $((\lambda y \text{ apple}) y) \text{apple}$
- C. $((\lambda y y) y)$
- D. apple

QUIZ

```
(( $\lambda x \rightarrow (x (\lambda x \rightarrow x))$ ) apple)
```

=> ???

- A. $(\text{apple } (\lambda x \rightarrow x))$
- B. $(\text{apple } (\lambda \text{apple} \rightarrow \text{apple}))$
- C. $(\text{apple } (\lambda x \rightarrow \text{apple}))$
- D. apple
- E. $(\lambda x \rightarrow x)$

EXERCISE

What is a λ -term `fill_this_in` such that

```
fill_this_in apple
=> banana
```

ELSA: <https://goto.ucsd.edu/elsa/index.html>

[Click here to try this exercise](#)

A Tricky One

```
(( $\lambda x \rightarrow (\lambda y \rightarrow x)$ ) y)
```

=> $\lambda y \rightarrow y$

Is this right?

Something is Fishy

```
( $\lambda x \rightarrow (\lambda y \rightarrow x)$ ) y
```

=> $(\lambda y \rightarrow y)$

Is this right?

Problem: The *free* y in the argument has been **captured** by λy in body!

Solution: Ensure that *formals* in the body are **different** from *free-variables* of argument!

Capture-Avoiding Substitution

We have to fix our definition of β -reduction:

```
( $\lambda x \rightarrow e_1$ )  $e_2$   =>   $e_1[x := e_2]$ 
```

where $e_1[x := e_2]$ means " ~~e_1 with all free occurrences of x replaced with e_2~~ "

- e_1 with all free occurrences of x replaced with e_2
- as long as no free variables of e_2 get captured

Formally:

```
 $x[x := e]$       =  $e$ 
 $y[x := e]$       =  $y$           -- as  $x \neq y$ 
```

```
 $(e_1 e_2)[x := e]$  =  $(e_1[x := e]) (e_2[x := e])$ 
```

```
 $(\lambda x \rightarrow e_1)[x := e]$  =  $(\lambda x \rightarrow e_1)$   -- Q: Why leave 'e1' unchanged?
```

```
 $(\lambda y \rightarrow e_1)[x := e]$ 
| not (y in FV(e)) =  $\lambda y \rightarrow e_1[x := e]$ 
```

Oops, but what to do if y is in the *free-variables* of e ?

- i.e. if $\lambda y \rightarrow \dots$ may *capture* those free variables?

Rewrite Rules of Lambda Calculus

1. β -step (aka *function call*)
2. α -step (aka *renaming formals*)

Semantics: α -Renaming

```
 $\lambda x \rightarrow e$   =>   $\lambda y \rightarrow e[x := y]$ 
  where not (y in FV(e))
```

- We rename a formal parameter x to y
- By replace all occurrences of x in the body with y
- We say that $\lambda x \rightarrow e$ α -steps to $\lambda y \rightarrow e[x := y]$

Example:

```
( $\lambda x \rightarrow x$ )  =>   $(\lambda y \rightarrow y)$   =>   $(\lambda z \rightarrow z)$ 
```

All these expressions are α -equivalent

What's wrong with these?

```
-- (A)
 $(\lambda f \rightarrow (f x))$   =>   $(\lambda x \rightarrow (x x))$ 
```

```
-- (B)
 $((\lambda x \rightarrow (\lambda y \rightarrow y)) y)$   =>   $((\lambda x \rightarrow (\lambda z \rightarrow z)) z)$ 
```

Tricky Example Revisited

```
(( $\lambda x \rightarrow (\lambda y \rightarrow x)$ ) y)  -- rename 'y' to 'z' to avoid capture
=>  $((\lambda x \rightarrow (\lambda z \rightarrow x)) y)$ 
=>  $(\lambda z \rightarrow y)$   -- now do  $\beta$ -step without capture!
```

To avoid getting confused,

- you can **always** rename formals,
- so different **variables** have different names!

Normal Forms

Recall **redex** is a λ -term of the form

```
(( $\lambda x \rightarrow e_1$ )  $e_2$ )
```

A λ -term is in **normal form** if it contains no redexes.

QUIZ

Which of the following terms are not in normal form?

- A. x
- B. (x y)
- C. ((\x -> x) y)
- D. (x (\y -> y))
- E. C and D

Semantics: Evaluation

A *i*-term *e* evaluates to *e'* if

1. There is a sequence of steps

$e \Rightarrow^? e_1 \Rightarrow^? \dots \Rightarrow^? e_N \Rightarrow^? e'$

where each $\Rightarrow^?$ is either \Rightarrow or \rightarrow and $N \gg 0$

2. e' is in normal form

Examples of Evaluation

((\x -> x) apple)

=> apple

(\f -> f (\x -> x)) (\x -> x)

=> ???

(\x -> x x) (\x -> x)

=> ???

Elsa shortcuts

Named *i*-terms:

let ID = (\x -> x) -- abbreviation for (\x -> x)

To substitute name with its definition, use a => step:

(ID apple)
=> ((\x -> x) apple) -- expand definition
=> apple -- beta-reduce

Evaluation:

- $e_1 \Rightarrow^? e_2$: e_1 reduces to e_2 in 0 or more steps
 - where each step is \Rightarrow , \rightarrow , or \Rightarrow
- $e_1 \Rightarrow^? e_2$: e_1 evaluates to e_2 and e_2 is in normal form

EXERCISE

Fill in the definitions of FIRST, SECOND and THIRD such that you get the following behavior in Elsa

```
let FIRST = fill_this_in
let SECOND = fill_this_in
let THIRD = fill_this_in
```

```
eval ex1 :
FIRST apple banana orange
=> apple
```

```
eval ex2 :
SECOND apple banana orange
=> banana
```

```
eval ex3 :
THIRD apple banana orange
=> orange
```

ELSA: <https://goto.ucsd.edu/elsa/index.html>

[Click here to try this exercise](#)

Non-Terminating Evaluation

((\x -> (x x)) (\x -> (x x)))

=> ((\x -> (x x)) (\x -> (x x)))

Some programs loop back to themselves... never reduce to a normal form!

This combinator is called Ω

What if we pass Ω as an argument to another function?

```
let OMEGA = ((\x -> (x x)) (\x -> (x x)))
```

```
((\x -> (\y -> y)) OMEGA)
```

Does this reduce to a normal form? Try it at home!

C *calculus*

Programming in λ -calculus

Real languages have lots of features *OO-features* \rightarrow Friday

$e ::= x \mid e_1 e_2 \mid \lambda x. e$

- Booleans
 - Records (structs, tuples)
 - Numbers
 - Lists
 - Functions [we got those]
 - Recursion

Let's see how to encode all of these features with the λ -calculus

$(\lambda x. \lambda y. x)$ apple \Rightarrow apple
 $(\lambda x. \lambda y. x)$ apple \Rightarrow y
 $(\lambda x. e)$ $e' \Rightarrow e[x \leftarrow e']$

ITE cond x y
 "IF cond THEN e_1 ELSE e_2 "
 "cond is 'true'" $\Rightarrow e_1$
 "cond is 'false'" $\Rightarrow e_2$

"true" $\equiv (\lambda x. \lambda y. x)$ apple banana \Rightarrow
 "false" $\equiv \lambda x. \lambda y. y$

Syntactic Sugar

$\lambda x_1 \dots x_n. y \rightarrow \text{BODY}$ $(\lambda x. \lambda y. (\lambda z. \text{BODY}))$

instead of $\lambda x. \lambda y. (\lambda z. (\lambda x. \lambda y. \lambda z. \rightarrow e))$ we write $\lambda x. \lambda y. \lambda z. \rightarrow e$

$\lambda x. \lambda y. \lambda z. \rightarrow e$ $\lambda x. \lambda y. z. \rightarrow e$

$((e_1 e_2) e_3) e_4$ $e_1 e_2 e_3 e_4$

$((e_1 e_2) e_3) e_4$

$\lambda x y. \rightarrow y$ -- A function that takes two arguments and returns the second one...

$(\lambda x y. \rightarrow y)$ apple banana ... applied to two arguments

λ -calculus: Booleans

How can we encode Boolean values (TRUE and FALSE) as functions?

Well, what do we do with a Boolean b?

Make a binary choice

- if b then e_1 else e_2

Booleans: API

We need to define three functions

```
let TRUE = \x y. x
let FALSE = \x y. y
```

```
let ITE = \b x y. b x y -- if b then x else y
```

such that $(\lambda b. \lambda x. \lambda y. b x y)$ (b x y)

```
ITE TRUE apple banana => apple
ITE FALSE apple banana => banana
```

(Here, let NAME = e means NAME is an abbreviation for e)

Booleans: Implementation

```
let TRUE = \x y. x -- Returns its first argument
let FALSE = \x y. y -- Returns its second argument
let ITE = \b x y. b x y -- Applies condition to branches
-- (redundant, but improves readability)
```

Example: Branches step-by-step

```
eval ite_true:
ITE TRUE e1 e2
=> (\b x y. b x y) TRUE e1 e2 -- expand def ITE
=> (\b x y. b x y) TRUE e1 e2 -- beta-step
=> (\y -> TRUE e1 y) e2 -- beta-step
=> TRUE e1 e2 -- expand def TRUE
=> (\x y -> x) e1 e2 -- beta-step
=> (\y -> e1) e2 -- beta-step
=> e1
```

Example: Branches step-by-step

Now you try it!
Can you fill in the blanks to make it happen?

```
eval ite_false:
ITE FALSE e1 e2
```

```
-- fill the steps in!
```

```
=> e2
```

EXERCISE: Boolean Operators

ELSA: <https://goto.ucsd.edu/elsa/index.html> [Click here to try this exercise](#)

Now that we have ITE it's easy to define other Boolean operators:

```
let NOT = \b. b FALSE TRUE
```

```
let OR = \b1 b2. b1 b2 || b1 b2 -- if (b1 true) TRUE TRUE
```

```
let AND = \b1 b2. b1 b2 && b1 b2 -- if b FALSE TRUE
```

When you are done, you should get the following behavior:

```
eval ex_not_t:
NOT TRUE => FALSE
```

```
eval ex_not_f:
NOT FALSE => TRUE
```

```
eval ex_or_ff:
OR FALSE FALSE => FALSE
```

```
eval ex_or_ft:
OR FALSE TRUE => TRUE
```

```
eval ex_or_ft:
OR TRUE FALSE => TRUE
```

```
eval ex_or_tt:
OR TRUE TRUE => TRUE
```

```
eval ex_and_ff:
AND FALSE FALSE => FALSE
```

```
eval ex_and_ft:
AND FALSE TRUE => FALSE
```

```
eval ex_and_ft:
AND TRUE FALSE => FALSE
```

```
eval ex_and_tt:
AND TRUE TRUE => TRUE
```

Programming in λ -calculus

Booleans [done]

- Records (structs, tuples)
- Numbers
- Lists
- Functions [we got those]
- Recursion

λ -calculus: Records

Let's start with records with two fields (aka pairs)

What do we do with a pair?

1. Pack two items into a pair, then
2. Get first item, or
3. Get second item.

FIRST (PAIR apple banana) \Rightarrow apple

SECOND (PAIR apple banana) \Rightarrow banana

FST BOX \rightarrow apple

SND BOX \rightarrow banana

BOX $\equiv \lambda b. \lambda x. b x$ \rightarrow apple banana

FST BOX \equiv BOX TRUE \rightarrow apple

SND BOX \equiv BOX FALSE \rightarrow banana

Pairs: API

We need to define three functions

```
let PAIR = \x y. ??? -- Make a pair with elements x and y
```

```
let FST = \p. ??? -- {fst : x, snd : y}
```

```
let SND = \p. ??? -- p.fst
```

such that

```
eval ex_fst:
FST (PAIR apple banana) => apple
```

```
eval ex_snd:
SND (PAIR apple banana) => banana
```

Pairs: Implementation

A pair of x and y is just something that lets you pick between x and y

```
let PAIR = \x y. (\b. b -> ITE b x y)
```

ie. PAIR x y is a function that

- takes a boolean and returns either x or y

We can now implement FST and SND by "calling" the pair with TRUE or FALSE

```
let FST = \p -> p TRUE -- call w/ TRUE, get first value
```

```
let SND = \p -> p FALSE -- call w/ FALSE, get second value
```

EXERCISE: Triples

How can we implement a record that contains three values?

ELSA: <https://goto.ucsd.edu/elsa/index.html>

[Click here to try this exercise](#)

```
let TRIPLE = \x y z. ??? PAIR (PAIR x y) z
```

```
let FST3 = \t. ??? FST (FST t)
```

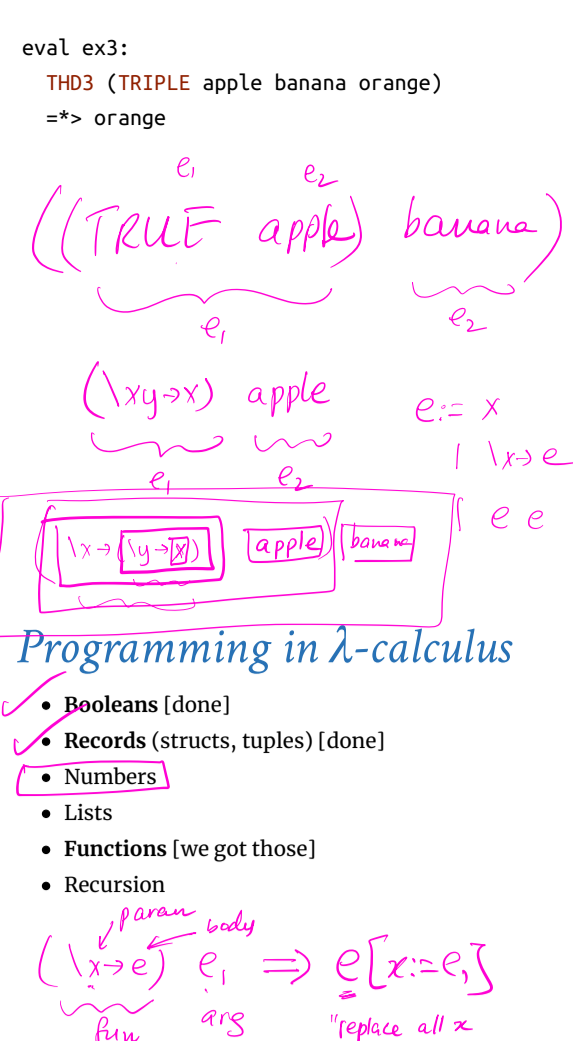

```
let SND3 = \t. ??? SND (FST t)
```

```
let THD3 = \t. ??? SND t
```

```
eval ex1:
FS3 (TRIPLE apple banana orange)
=> apple

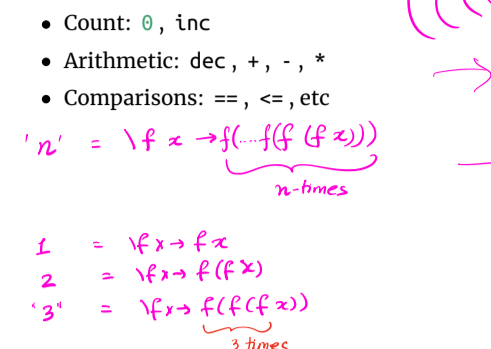

eval ex2:
SN3 (TRIPLE apple banana orange)
=> banana

eval ex3:
TH3 (TRIPLE apple banana orange)
=> orange
```

Programming in lambda-calculus

- Booleans [done]
- Records (structs, tuples) [done]
- Numbers
- Lists
- Functions [we got those]
- Recursion

lambda-calculus: Numbers => (lambda (x1) (lambda (x2) (lambda (x3) BODY)))

Let's start with natural numbers (0, 1, 2, ...)

What do we do with natural numbers?

- Count: 0, inc
 - Arithmetic: dec, +, -, *
 - Comparisons: =, <=, etc
- 'n' = lambda f x => f(f(f(x)))
- 1 = lambda f x => f(x)
 2 = lambda f x => f(f(x))
 3 = lambda f x => f(f(f(x)))

Natural Numbers: API

We need to define:

- A family of numerals: ZERO, ONE, TWO, THREE, ...
- Arithmetic functions: INC, DEC, ADD, SUB, MULT
- Comparisons: IS_ZERO, EQ

Such that they respect all regular laws of arithmetic, e.g.

```
IS_ZERO ZERO ==> TRUE
IS_ZERO (INC ZERO) ==> FALSE
INC ONE ==> TWO
...
```

Natural Numbers: Implementation

Church numerals: a number N is encoded as a combinator that calls a function on an argument N times

```
let ONE = lambda f x -> f x
let TWO = lambda f x -> f (f x)
let THREE = lambda f x -> f (f (f x))
let FOUR = lambda f x -> f (f (f (f x)))
let FIVE = lambda f x -> f (f (f (f (f x))))
let SIX = lambda f x -> f (f (f (f (f (f x))))))
...
```

QUIZ: Church Numerals

Which of these is a valid encoding of ZERO ?

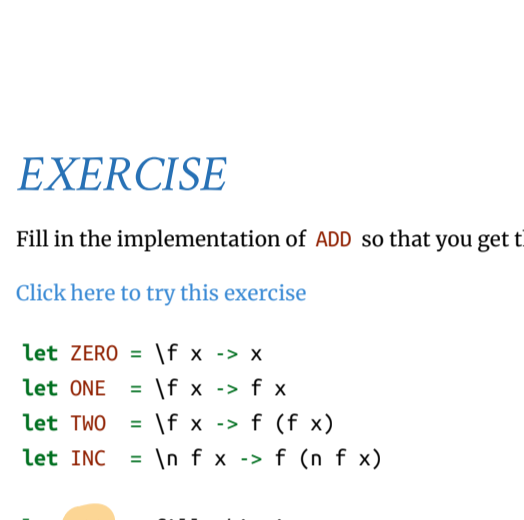

- A: let ZERO = lambda f x -> x
- B: let ZERO = lambda f x -> f
- C: let ZERO = lambda f x -> f x
- D: let ZERO = lambda x -> x
- E: None of the above

```
lambda f x -> x == ZERO
lambda x y -> y == FALSE
```

Does this function look familiar?

lambda-calculus: Increment

```
-- Call 'f' on 'x' one more time than 'n' does
let INC = lambda n -> (lambda f x -> ???)
```

Example:

```
eval inc_zero :
INC ZERO
=> (lambda f x -> f (n f x)) ZERO
=> (lambda f x -> f (ZERO f x))
=> (lambda f x -> f x)
=> ONE
```

EXERCISE

Fill in the implementation of ADD so that you get the following behavior

Click here to try this exercise

```
let ZERO = lambda f x -> x
let ONE = lambda f x -> f x
let TWO = lambda f x -> f (f x)
let INC = lambda n f x -> f (n f x)

let ADD = fill_this_in
```

```
eval add_zero_zero:
ADD ZERO ZERO ==> ZERO

eval add_zero_one:
ADD ZERO ONE ==> ONE

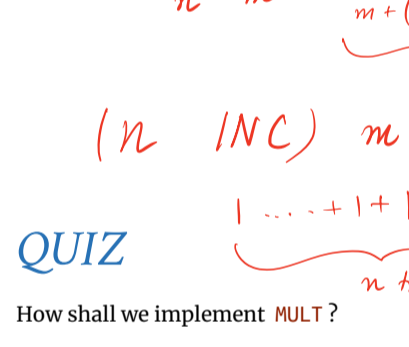

eval add_zero_two:
ADD ZERO TWO ==> TWO

eval add_one_zero:
ADD ONE ZERO ==> ONE

eval add_one_one:
ADD ONE ONE ==> TWO

eval add_two_zero:
ADD TWO ZERO ==> TWO
```

- A. let ADD = lambda n m -> (n INC m)
- B. let ADD = lambda n m -> (INC n) m
- C. let ADD = lambda n m -> n m INC
- D. let ADD = lambda n m -> n (m INC)
- E. let ADD = lambda n m -> n (INC m)

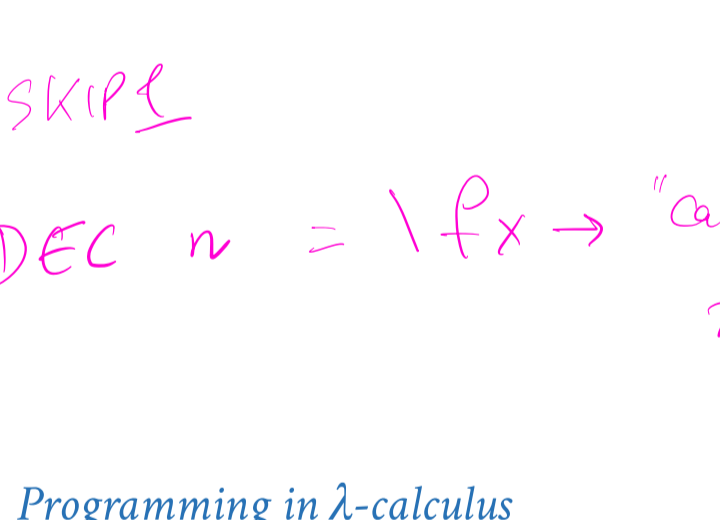

lambda-calculus: Addition

```
-- Call 'f' on 'x' exactly 'n + m' times
let ADD = lambda n m -> n INC m
```

Example:

```
eval add_one_zero :
ADD ONE ZERO
=> ONE
```

QUIZ

How shall we implement MULT ?

- A. let MULT = lambda n m -> n ADD m
- B. let MULT = lambda n m -> n (ADD n) ZERO
- C. let MULT = lambda n m -> m (ADD n) ZERO
- D. let MULT = lambda n m -> n (ADD m) ZERO
- E. let MULT = lambda n m -> (n ADD n) ZERO

lambda-calculus: Multiplication

```
-- Call 'f' on 'x' exactly 'n * m' times
let MULT = lambda n m -> n (ADD m) ZERO
```

Example:

```
eval two_times_three :
MULT TWO ONE
=> TWO
```

SKIP

DEC n = lambda f x -> "call f on x n-1 times" n f x

Programming in lambda-calculus

- Booleans [done]
- Records (structs, tuples) [done]
- Numbers [done]
- Lists
- Functions [we got those]
- Recursion

ISZERO = lambda n -> n (lambda f x -> FALSE) TRUE

case	I want	Result
n=0	TRUE	?x
n=1	FALSE	?(TRUE)
n=2	FALSE	?(?(TRUE))
n=3	FALSE	?(?(?(TRUE)))

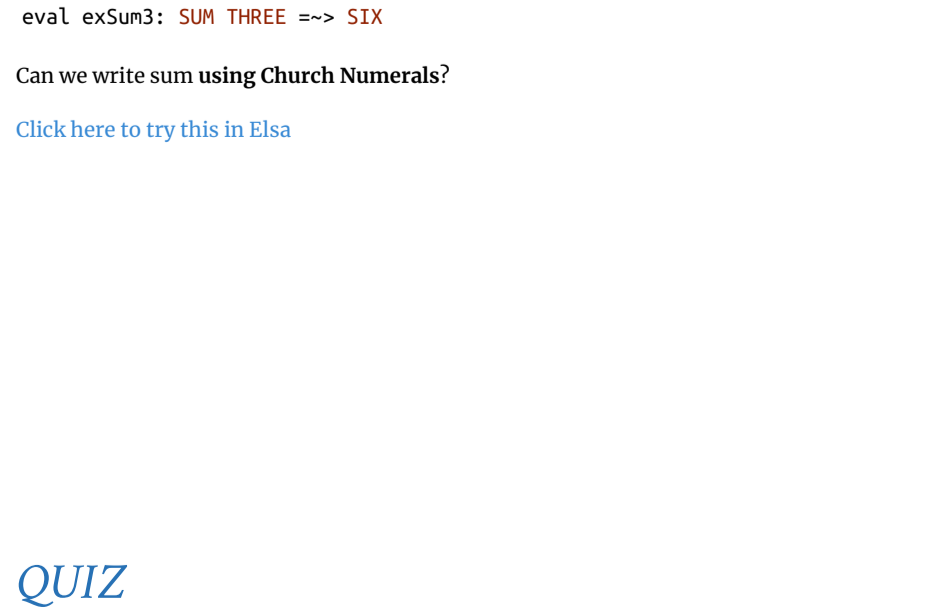

lambda-calculus: Lists

Lets define an API to build lists in the lambda-calculus.

1 An Empty List

NIL

2 Constructing a list

```
HEAD (CONS apple (CONS banana (CONS cantaloupe (CONS dragon NIL))))
=> apple

TAIL (CONS apple (CONS banana (CONS cantaloupe (CONS dragon NIL))))
=> CONS banana (CONS cantaloupe (CONS dragon NIL))
```

lambda-calculus: Lists

```
let NIL = ???
let CONS = ???
let HEAD = ???
let TAIL = ???
```

```
eval exHd:
HEAD (CONS apple (CONS banana (CONS cantaloupe (CONS dragon NIL))))
=> apple

eval exTL:
TAIL (CONS apple (CONS banana (CONS cantaloupe (CONS dragon NIL))))
=> CONS banana (CONS cantaloupe (CONS dragon NIL))
```

EXERCISE: Nth

Write an implementation of GetNth such that

- GetNth n l returns the n-th element of the list l

Assume that l has n or more elements

```
let GetNth = ???

eval nth1 :
GetNth ZERO (CONS apple (CONS banana (CONS cantaloupe NIL)))
=> apple

eval nth1 :
GetNth ONE (CONS apple (CONS banana (CONS cantaloupe NIL)))
=> banana

eval nth2 :
GetNth TWO (CONS apple (CONS banana (CONS cantaloupe NIL)))
=> cantaloupe
```

GetNth = lambda n l -> BST (n SND l)

lambda-calculus: Recursion

I want to write a function that sums up natural numbers up to n:

```
let SUM = lambda n -> ... (0 + 1 + 2 + ... + n)
```

such that we get the following behavior

```
eval exSum0: SUM ZERO ==> ZERO
eval exSum1: SUM ONE ==> ONE
eval exSum2: SUM TWO ==> THREE
eval exSum3: SUM THREE ==> SIX
```

Can we write sum using Church Numerals?

Click here to try this in Elsa

QUIZ

You can write SUM using numerals but its tedious.

Is this a correct implementation of SUM ?

```
let SUM = lambda n -> ITE (ISZ n)
ZERO
(ADD n (SUM (DEC n)))
```

- A. Yes
- B. No

No!

- Named terms in Elsa are just syntactic sugar
- To translate an Elsa term to λ -calculus: replace each name with its definition

```
\n -> ITE (ISZ n)
      ZERO
      (ADD n (SUM (DEC n))) -- But SUM is not yet defined!
```

Recursion:

- Inside *this* function
- Want to call the *same* function on `DEC n`

Looks like we can't do recursion!

- Requires being able to refer to functions *by name*,
- But λ -calculus functions are *anonymous*.

Right?

λ -calculus: Recursion

Think again!

Recursion:

Instead of

- ~~Inside this function I want to call the same function on DEC n~~

Lets try

- Inside *this* function I want to call *some* function `rec` on `DEC n`
- And BTW, I want `rec` to be the *same* function

Step 1: Pass in the function to call “recursively”

```
let STEP =
  \rec -> \n -> ITE (ISZ n)
            ZERO
            (ADD n (rec (DEC n))) -- Call some rec
```

Step 2: Do some magic to `STEP`, so `rec` is itself

```
\n -> ITE (ISZ n) ZERO (ADD n (rec (DEC n)))
```

That is, obtain a term `MAGIC` such that

```
MAGIC => STEP MAGIC
```

λ -calculus: Fixpoint Combinator

Wanted: a λ -term `FIX` such that

- `FIX STEP` calls `STEP` with `FIX STEP` as the first argument:

```
(FIX STEP) => STEP (FIX STEP)
```

(In math: a *fixpoint* of a function $f(x)$ is a point x , such that $f(x) = x$)

Once we have it, we can define:

```
let SUM = FIX STEP
```

Then by property of `FIX` we have:

```
SUM => FIX STEP => STEP (FIX STEP) => STEP SUM
```

and so now we compute:

```
eval sum_two:
SUM TWO
=> STEP SUM TWO
=> ITE (ISZ TWO) ZERO (ADD TWO (SUM (DEC TWO)))
=> ADD TWO (SUM (DEC TWO))
=> ADD TWO (SUM ONE)
=> ADD TWO (STEP SUM ONE)
=> ADD TWO (ITE (ISZ ONE) ZERO (ADD ONE (SUM (DEC ONE))))
=> ADD TWO (ADD ONE (SUM (DEC ONE)))
=> ADD TWO (ADD ONE (SUM ZERO))
=> ADD TWO (ADD ONE (ITE (ISZ ZERO) ZERO (ADD ZERO (SUM DEC ZERO))))
=> ADD TWO (ADD ONE (ZERO))
=> THREE
```

How should we define `FIX`???

The Y combinator

Remember Ω ?

```
(\x -> x x) (\x -> x x)
=> (\x -> x x) (\x -> x x)
```

This is *self-replicating code*! We need something like this but a bit more involved...

The Y combinator discovered by Haskell Curry:

```
let FIX = \stp -> (\x -> stp (x x)) (\x -> stp (x x))
```

How does it work?

```
eval fix_step:
FIX STEP
=> (\stp -> (\x -> stp (x x)) (\x -> stp (x x))) STEP
=> (\x -> STEP (x x)) (\x -> STEP (x x))
=> STEP ((\x -> STEP (x x)) (\x -> STEP (x x)))
-- ^^^^^^^^^^^ this is FIX STEP ^^^^^^^^^^^^^
```

That's all folks, Haskell Curry was very clever.

Next week: We'll look at the language named after him (`Haskell`)
